The second-class current

The weak hadronic currents without strangeness can be classified into two types depending on G-parity(G);

- $PG(-1)^J = +1$: first-class current (FCC)
- $PG(-1)^J = -1$: second-class current (SCC) ← not observed

(P is parity and J is spin of the decay current)

In the Standard Model, the SCC is strongly suppressed due to isospin symmetry and no such current has been observed so far.

The second-class current τ decay mode:

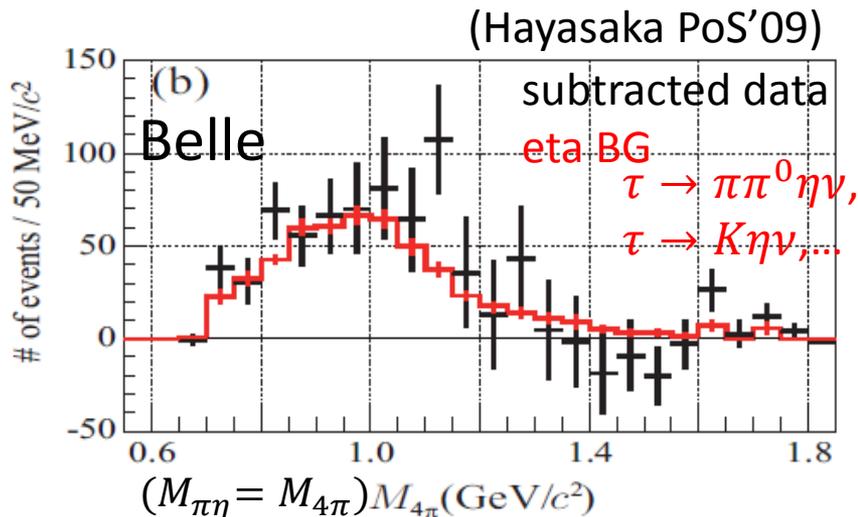

$$\tau \rightarrow \pi \eta \nu$$

For the second-class current τ decay, $\tau \rightarrow \pi \eta \nu$ ($J^{\text{PG}} = 0^{+-}$)

$\Rightarrow \tau \rightarrow \pi \eta \nu$ can be realized through the SCC.

$\tau \rightarrow \pi \eta \nu$ various theoretical predictions give for its branching fraction $O(10^{-5})$, that is reachable with the available Belle data sample.

We report status of our analysis of $\tau \rightarrow \pi \eta \nu$, based on Monte Carlo simulated samples corresponding to Belle full data.

Previous study:

$$\begin{aligned} \text{Br}^{\text{Belle}}(\tau^- \rightarrow \pi^- \eta \nu) @ 670 \text{fb}^{-1} &= (4.4 \pm 1.6 \pm 0.8) \times 10^{-5} (2.4\sigma) \\ &< 7.3 \times 10^{-5} \text{ CL}=90\% \text{ (un-published)} \end{aligned}$$

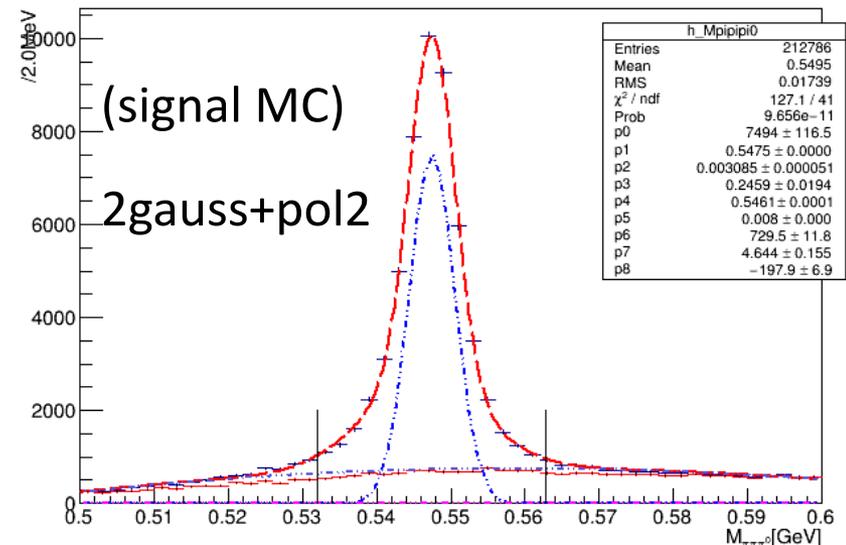

$$\begin{aligned} \text{Br}^{\text{BaBar}}(\tau^- \rightarrow \pi^- \eta \nu) @ 470 \text{fb}^{-1} &= (3.4 \pm 3.4 \pm 2.1) \times 10^{-5} \\ &< 9.9 \times 10^{-5} \text{ CL}=95\% \end{aligned}$$

(P.del Amo Sanchez et.al, PRD 83 032002(2011))

Hereafter, the $\text{Br}^{\text{Belle}}(\tau^- \rightarrow \pi^- \eta \nu) = 4.4 \times 10^{-5}$ is used as a reference.

$M_{\pi\pi\pi^0}$ distribution for signal MC

- Using selected events:
 - signal: $\tau \rightarrow \pi\eta(\eta \rightarrow \pi\pi\pi^0)\nu$ (The selection criteria is shown in poster)
 - Tag: $\tau \rightarrow l\nu\nu$ (leptonic tag)
- signal extraction: yield is evaluated by a fit for eta peak on $M_{\pi\pi\pi^0}$ distribution.**
 - using both $\pi^+\pi^-\pi^0$ combinations ($\tau^- \rightarrow \pi^-\pi^+\pi^-\pi^0\nu$)
- Fit with 2Gaussian + 2nd polynomial function. $M_{\pi\pi\pi^0}$ for signalMC
- Signal region is defined as $547 \pm 15\text{MeV}$ that corresponds to mean $\pm 5\sigma$ region of the main peak of the signal shape (blue gauss).
- $(4.64 \pm 0.03) \times 10^4$ events are obtained from 1.3×10^7 events..
- **Efficiency is $0.350 \pm 0.002\%$**

Main BG modes

Main BG modes are divided into the following.

Since $\tau \rightarrow \pi\eta\pi^0\nu$ and $K^*(\rightarrow K_L\pi)\eta\nu$ have much larger Br than expected Br for signal, their rates seriously affect the systematics.

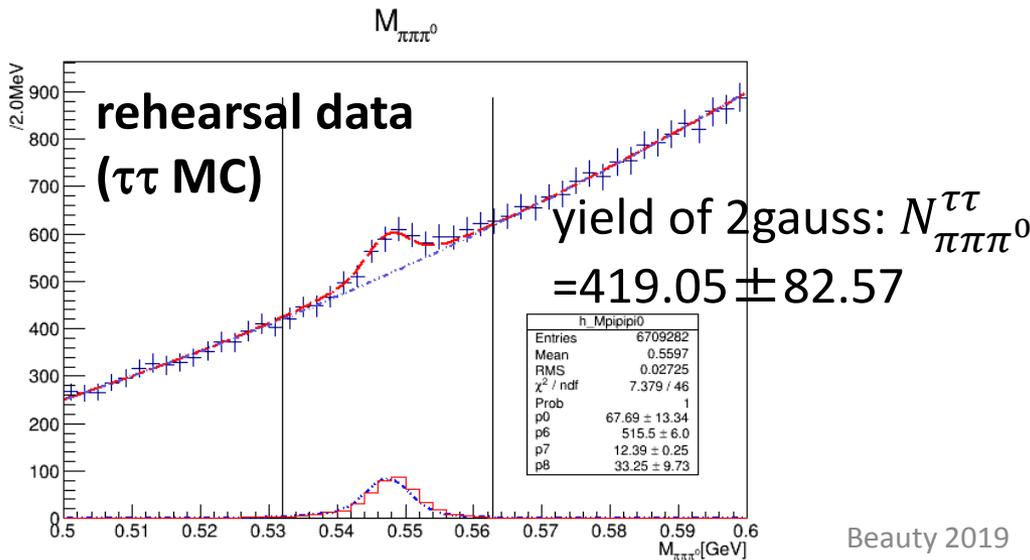

- η peaking BG
 - $\tau \rightarrow \pi\eta\pi^0\nu$ (π^0 missing):
Br=(1.39±0.07) × 10⁻³
 - $\tau \rightarrow K^*\eta\nu$, $K^* \rightarrow K_L\pi$ (K_L missing):
Br=(1.38±0.15) × 10⁻⁴
 - $\tau \rightarrow K\eta\nu$ (Pid misidentification):
Br= (1.55±0.08) × 10⁻⁴
 - $q\bar{q}$ including π and η
- Non-peaking BG
 - $\tau \rightarrow \pi\pi\pi\pi^0\nu$:
Br=(4.62±0.05)%
 - $\tau \rightarrow \pi\pi\pi\nu$ with fake π^0

η signal extraction

- For the demonstration, we consider $\tau\tau$ MC sample as a 702 fb^{-1} data samples here. (rehearsal data)
- The signal yield is estimated by the difference:

$$N_{\pi\pi\pi^0}^{\tau\tau} - \left(N_{\pi\pi\pi^0}^{K\eta\nu} + N_{\pi\pi\pi^0}^{K^*\eta\nu} + N_{\pi\pi\pi^0}^{\pi\pi^0\eta\nu} (+N_{\pi\pi\pi^0}^{q\bar{q}}) \right) = 16.06 \pm 86.04$$

Since $\tau\tau$ MC don't have $\tau \rightarrow \pi\eta\nu$ events, this yield is expected to be 0.

Beauty 2019

Main peak BG	# of η for 702 fb^{-1} samples
$\tau \rightarrow K\eta\nu$	$N_{\pi\pi\pi^0}^{K\eta\nu} = 35.15 \pm 2.24$
$\tau \rightarrow K^*\eta\nu$	$N_{\pi\pi\pi^0}^{K^*\eta\nu} = 113.98 \pm 4.07$
$\tau \rightarrow \pi\pi^0\eta\nu$	$N_{\pi\pi\pi^0}^{\pi\pi^0\eta\nu} = 259.09 \pm 6.13$
$q\bar{q}$	$N_{\pi\pi\pi^0}^{q\bar{q}} = 72.85 \pm 14.10$

($N_{\pi\pi\pi^0}^{q\bar{q}}$ is included into error only)

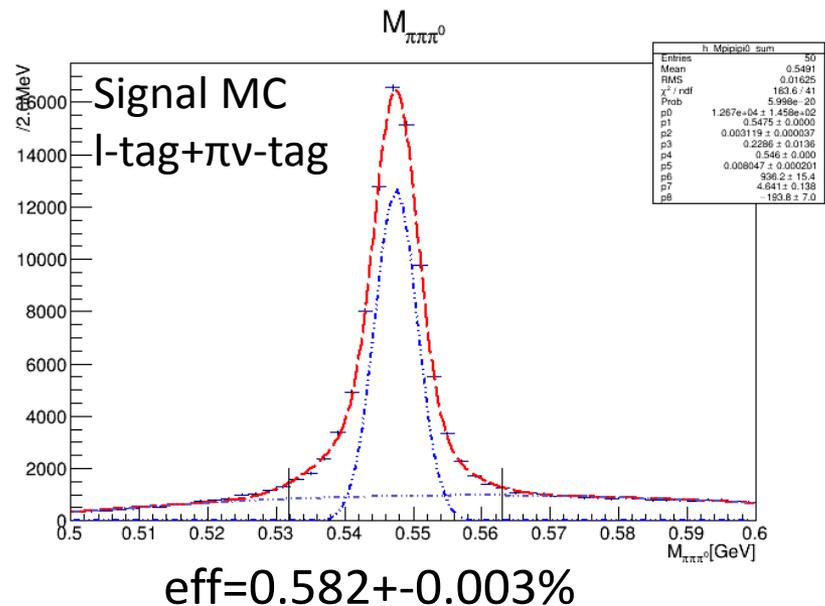

Evaluated significance

- Evaluate significance with Υ_{4S} data (703fb^{-1}) and full data (915fb^{-1} : $\Upsilon_{4S}, \Upsilon_{5S}$, continuum)
- When number of signal N_{sig} and significance are defined as $2\epsilon' N_{\tau\tau pair} Br(\tau \rightarrow \pi\eta\nu)$ and $\frac{N_{sig}}{N_{sigerr}}$ (detection efficiency $\epsilon' = 0.350\%$ by signal MC), significances for each assumption of luminosity L and $Br(\tau \rightarrow \pi\eta\nu)$ are shown in the table below.

$Br(\tau \rightarrow \pi\eta\nu)$	L, fb^{-1}	N_{sig}	significance, σ
4.4×10^{-5}	702.9	245	2.3
	915.1	259	2.6
1.0×10^{-5}	702.9	45	0.5
	915.1	59	0.6

Included hadronic tag ($\tau \rightarrow \pi\nu$)

- Allow not only leptonic tag but $\tau \rightarrow \pi\nu$ (Br=10.82%) in tag side
- According to naive estimation that multiplied by square root of efficiency increase, the significance is 3.4σ ($=2.6\sigma \times \sqrt{\frac{0.582}{0.350}}$) for $\text{Br}(\tau \rightarrow \pi\eta\nu) = 4.4 \times 10^{-5}$ and full data.

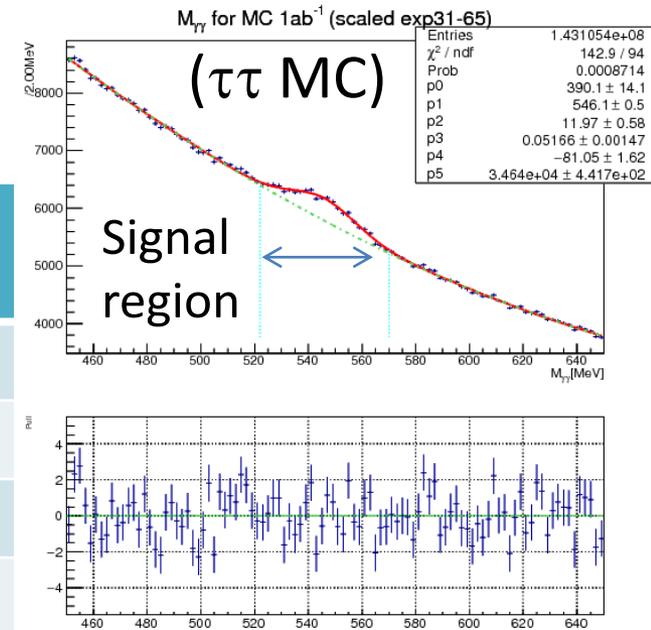

$\tau \rightarrow \pi\eta\nu, \eta \rightarrow \gamma\gamma$

- According to rough estimations, the rough significance is 0.7σ for $\mathcal{L} = 915.1\text{fb}^{-1}$ and $\text{Br}(\tau \rightarrow \pi\eta\nu) = 1.0 \times 10^{-5}$.
- But it turns out that this also has similar significance. This should be also seriously considered later.

Efficiency for signal MC = 1.50%.

$$\text{Rough significance}[\sigma] = \frac{N_{sig}}{\sqrt{\# \text{ of BG} + N_{sig}}}$$

$Br(\tau \rightarrow \pi\eta\nu)$	L, fb^{-1}	N_{sig}	# of BG	Rough significance, σ
4.4×10^{-5}	702.9	853	1.0×10^5	2.7
	915.1	1111	1.3×10^5	3.0
1.0×10^{-5}	702.9	194	1.0×10^5	0.6
	915.1	253	1.3×10^5	0.7

Summary

- In order to search for $\tau \rightarrow \pi\eta\nu$, we study the sensitivity using $\tau \rightarrow \pi\eta\nu$ with $\eta \rightarrow \pi\pi\pi^0$, based on Monte Carlo simulated samples corresponding to Belle's full data.
- We evaluate significance with full data (915fb^{-1} : $\Upsilon_{4S}, \Upsilon_{5S}$, continuum). It is 2.6σ for $Br(\tau \rightarrow \pi\eta\nu) = 4.4 \times 10^{-5}$ or 0.6σ for $Br(\tau \rightarrow \pi\eta\nu) = 1.0 \times 10^{-5}$.
- If the hadronic tag ($\tau \rightarrow \pi\nu$) is included, according to naive estimation that multiplied by square root of efficiency increase, the significance is 3.4σ for $Br(\tau \rightarrow \pi\eta\nu) = 4.4 \times 10^{-5}$ and full data.
- For $\tau \rightarrow \pi\eta\nu$ with $\eta \rightarrow \gamma\gamma$, 3.0σ may be expected with $Br(\tau \rightarrow \pi\eta\nu) = 4.4 \times 10^{-5}$ and full data. We need to study it more seriously to combine.

Back Up

$\tau \rightarrow \pi\eta\nu, \eta \rightarrow \pi\pi\pi^0$ selection criteria

- Definition of good charged track
 - $P_t > 0.06\text{GeV}/c^2$ in Barrel ($-0.6235 < \cos\theta < 0.8332$)
 $P_t > 0.1\text{GeV}/c^2$ in Endcap
($-0.8660 < \cos\theta \leq -0.6235, 0.8332 \leq \cos\theta < 0.9563$)
 - helix: $|dr| \leq 1\text{cm}, |dz| \leq 5\text{cm}$
- Definition for good gamma
 - $-0.8660 < \cos\theta < 0.9563$ & $E_\gamma > 0.05\text{GeV}$
- Missing angle at lab frame: $-0.8660 < \cos\theta_{miss} < 0.9563$

θ_{miss} is the polar angle for missing momentum P_{miss}
(difference between four-momentums for beam and sums of them for tracks and gammas).

$$P_{miss} = P_{beam} - \Sigma P^{tracks} + \Sigma P^\gamma$$

$\tau \rightarrow \pi\eta\nu, \eta \rightarrow \pi\pi\pi^0$ selection criteria

- Divide the event by the thrust vector into two hemispheres - the tag and signal sides which have 3-1 prong and net charge = 0.

- Tag side (leptonic tag; $\tau \rightarrow l\nu$):

Allow 1 lepton and $\leq 1\gamma$

to accept FSR or ISR from lepton.

invariant mass of all tag-side γ and track:

$$M_{tag} < 1.8\text{GeV}/c^2$$

- Signal side:

Allow 3π and 2γ only

($0.105 < M_{\gamma\gamma} < 0.165\text{GeV}$).

$$M_{sig} < 1.2\text{GeV}/c^2$$

- signal extraction: yield is evaluated by a fit for eta peak on $M_{\pi\pi\pi^0}$ distribution.
