# Pulsar Timing Arrays (PTA)

- ▶ **pulsars** are magnetized and rapidly rotating neutron stars; sources of radio waves
- ▶ the core of the sensitivity to **gravitational waves** using pulsars is in the change of the time of arrival of the signal
- ▶ PTA include analysis of large number of pulsars:
  - ▶ Parkes Pulsar Timing Arrays (25)
  - ▶ EPTA (42)
  - ▶ **NANOGrav** (47)
- ▶ So far, PTA measurement were able to report limits on the stochastic gravitational wave background at the level of  $\Omega h^2 \sim 10^{-8}$
- ▶ In contrast, recently NANOGrav reported a **strong preference for a stochastic common spectrum process** in 12.5-year data set analysis ([arXiv:2009.04496](https://arxiv.org/abs/2009.04496))

# NANOGrav Findings

- ▶ despite a very strong hint, these results are still **inconclusive** with respect to GW discovery
- ▶ **missing piece** : quadrupolar spatial correlation (Hellings & Downs, 1983)

- ▶ for the signal from  $i$ -th pulsar :

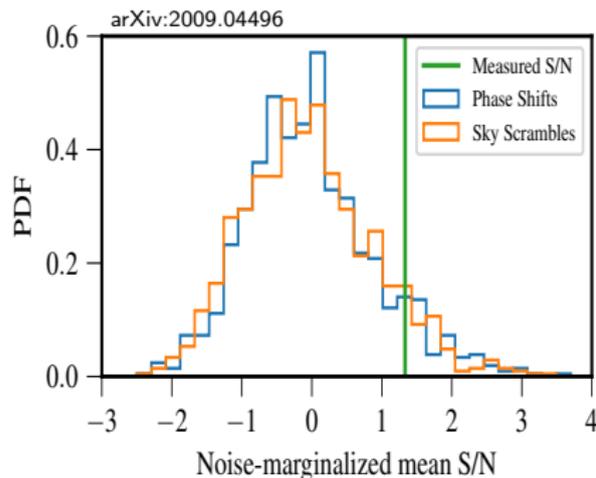

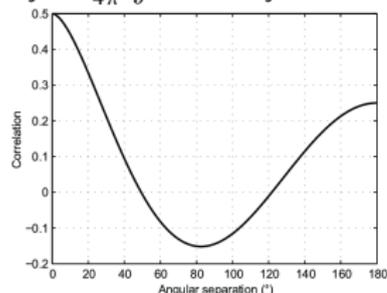

$$\alpha_i h(t) + n_i(t)$$

- ▶ cross-correlation from two pulsars :

$$\alpha_i \alpha_j \langle h^2 \rangle + \alpha_i \langle h n_j \rangle + \alpha_j \langle n_i h \rangle + \langle n_i n_j \rangle$$

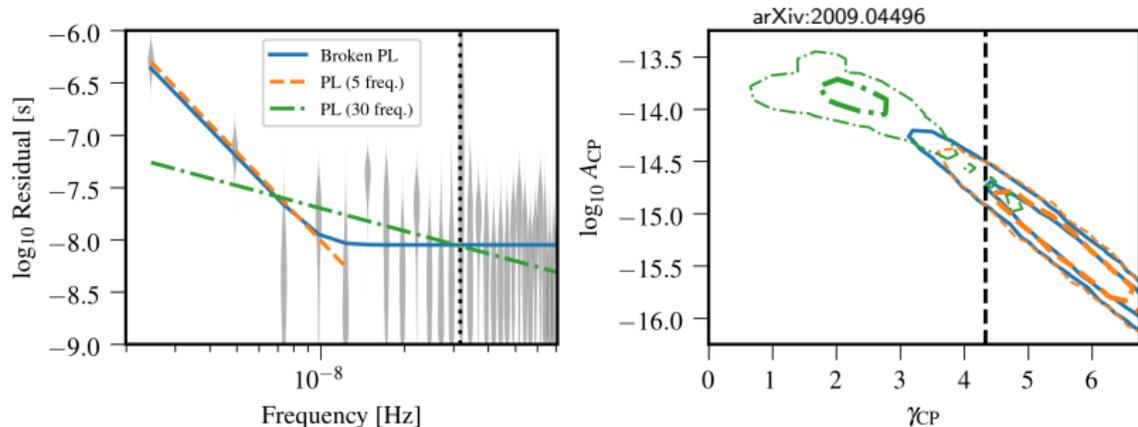

- ▶  $\langle h^2 \rangle = \frac{1}{T} \int_{-T}^{T+\tau} h(t) h(t + \tau) dt$

$$\alpha_{ij} = \frac{1}{4\pi} \int d\Omega \alpha_i \alpha_j \quad \text{arXiv:2002.01954}$$

- ▶ for no correlation hypothesis, large p-value at the level of 5%

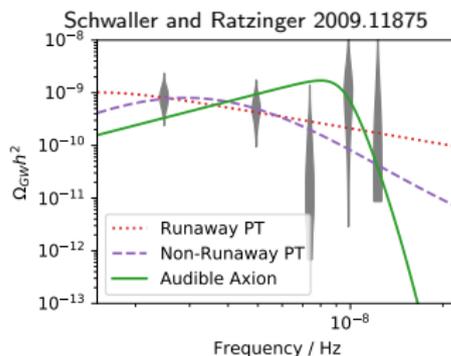

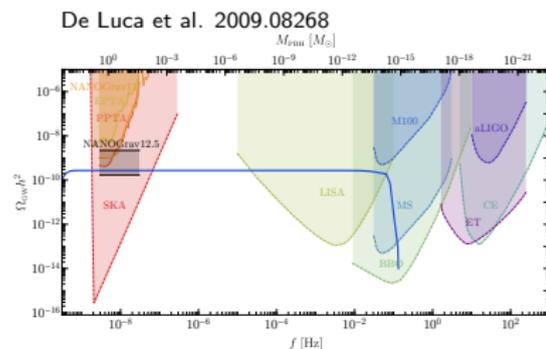

# NANOGrav Findings

- ▶ median value of  $A_{CP}$  higher than the 95% CL upper limit from 11 year data set!
- ▶ change in the data processing procedure led to the reduction in the amount of white noise which increases the sensitivity to low-frequency red noise processes  
⇒ stochastic gravitational waves
- ▶ free spectrum, 5-frequency power law and broken power law cases capture correctly lowest frequencies where GWs are detectable
- ▶ one of prime candidates for stochastic GW signal at  $f \sim n\text{Hz}$  are supermassive black hole binaries (distribution as a function of mass and redshift uncertain)

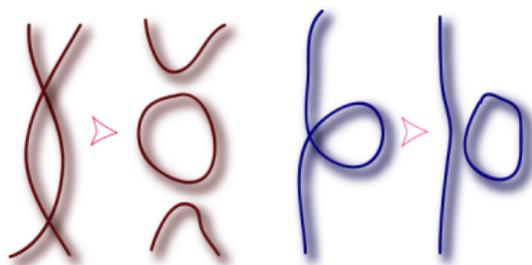

# Viable explanations

- ▶ assuming the discovery of quadrupolar spatial correlations will occur, a number of scenarios could be responsible for such stochastic GW signal:
- ▶ Cosmic strings (2009.06607, 2009.06555, 2009.10649, 2009.13452)
- ▶ First-order phase transition (2009.09754, 2009.10327, 2009.11875)
- ▶ Inflation (2009.13432)
- ▶ Primordial Black Holes (2009.07832, 2009.08268, 2009.11853)

# Cosmic Strings

- ▶ cosmic strings are topological defects  $\implies$  physical objects produced in the phase transitions (postulated by Kibble 1976)
- ▶ characterized by their tension  $\mu$
- ▶ long strings intersect and form loops which oscillate and radiate energy

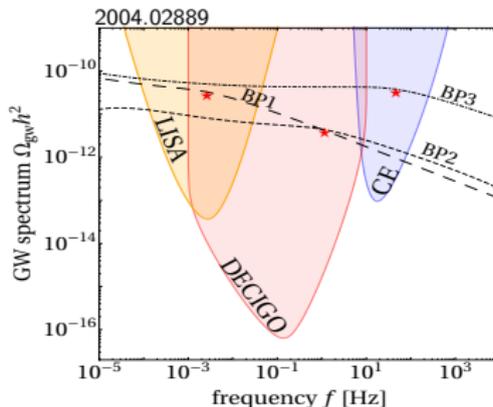

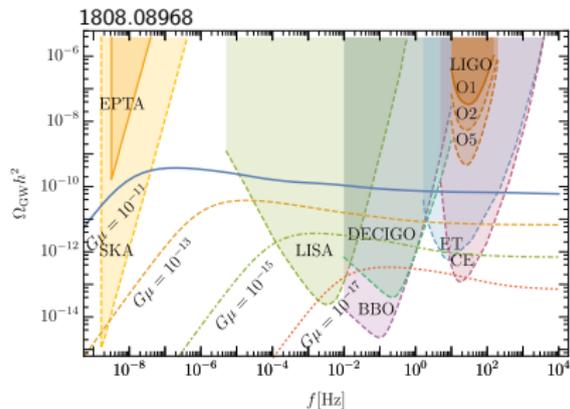

- ▶ dominant radiation in form of gravitational waves (string dynamics described in terms of Nambu-Goto action)
- ▶ GW emission from long strings can be neglected compared to the GW emission from loops

# Gravitational Wave Signature

1711.03104, 1808.08968, 1909.00819

$$\Omega_{\text{gw}}(f) = \sum_{k=1}^{\infty} \Omega_{\text{gw}}^{(k)}(f) = \frac{8\pi}{3H_0^2} (G\mu)^2 f \sum_{k=1}^{\infty} C_k P_k$$

- ▶  $P_k = \frac{\Gamma}{k^q \zeta(q)}$ ;  $q = 4/3$  for cusp-dominated loops and  $\Gamma \approx 50$
- ▶  $C_k(f) = \frac{2k}{f^2} \int_{t_{\text{scl}}}^{t_0} dt \Theta(t) \left( \frac{a(t)}{a(t_0)} \right)^5 n(\ell_k, t)$
- ▶ number of loops per unit volume  $n(\ell_k, t)$  and length depends on  $G\mu$  and parameter describing loop length at formation  $\alpha$

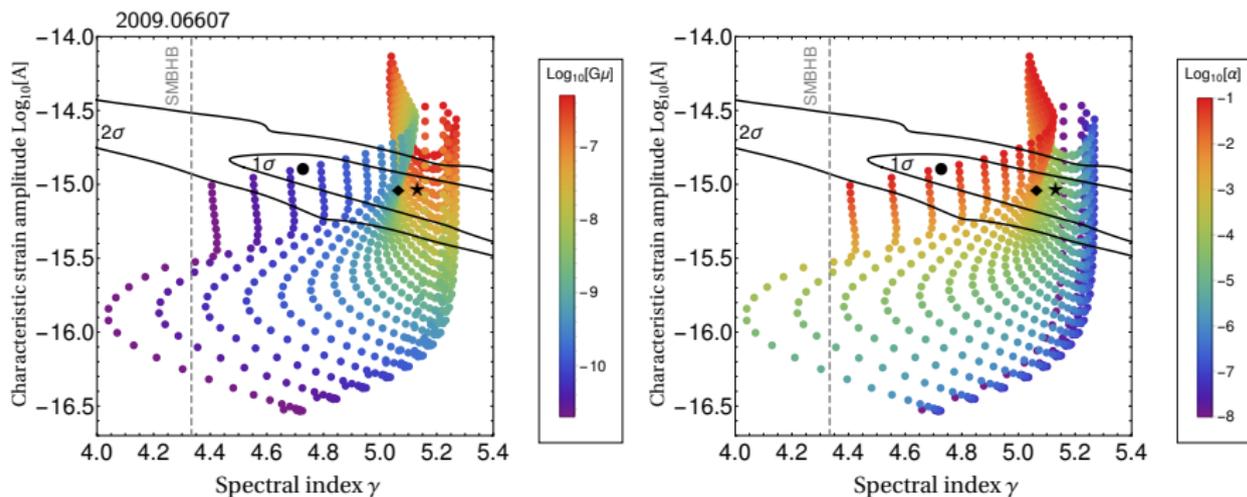

# Cosmic String Explanation of NANOGrav Result

- ▶ NANOGrav models the cross power spectrum around a reference frequency by a single power law  $S \propto (f/f_{ref})^{-\gamma}$
- ▶ can be expressed in terms of characteristic strain  $h_c(f) = A \left(\frac{f}{f_{ref}}\right)^{(3-\gamma)/2}$
- ▶ spectral GW energy density  $\Omega_{gw}(f) = \frac{2\pi^2}{3H_0^2} f^2 h_c^2(f) = \frac{2\pi^2}{3H_0^2} f_{ref}^2 A^2 \left(\frac{f}{f_{ref}}\right)^{5-\gamma}$
- ▶ by having  $\Omega_{gw}$  as a function of both  $(G\mu, \alpha)$  and  $(A, \gamma)$  we can determine the latter from the chosen  $(G\mu, \alpha)$  combination
- ▶ for all points in the scan, we check that a simple power-law fit provides a good approximation of the actual GW spectrum in the frequency range  $f \sim [3 \times 10^{-9}, 3 \times 10^{-8}]$  Hz where NANOGrav observes the signal

	$\alpha$	$G\mu$	$\gamma$	$A$
★	$6.0 \times 10^{-5}$	$1.0 \times 10^{-7}$	5.13	$9.25 \times 10^{-16}$
◆	$2.4 \times 10^{-3}$	$2.4 \times 10^{-9}$	5.06	$9.20 \times 10^{-16}$
●	$1.0 \times 10^{-1}$	$6.0 \times 10^{-11}$	4.73	$1.28 \times 10^{-15}$

# Cosmic String Explanation of NANOGrav Result

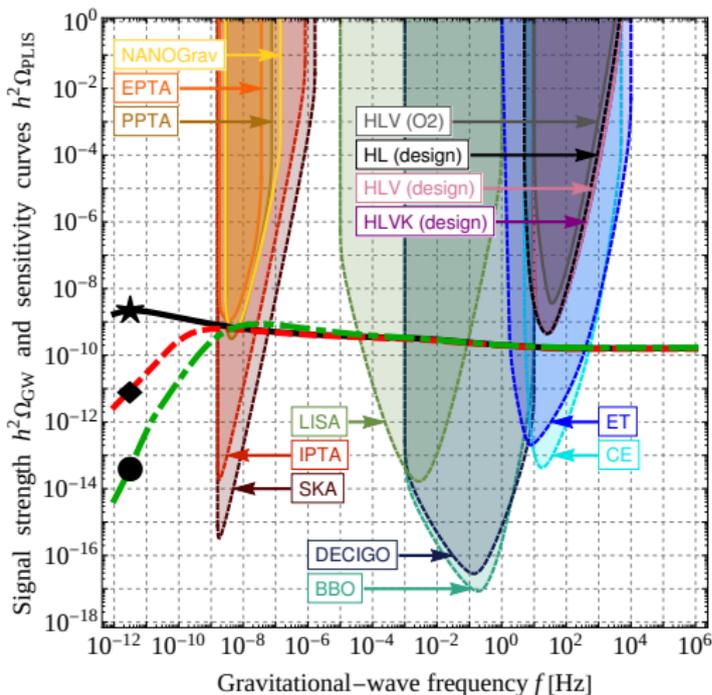

- ▶ we find that the cosmic-string-induced GW spectrum manages to reproduce the NANOGrav signal across large ranges of the parameters  $G\mu$  and  $\alpha$ ; **NANOGrav  $1\sigma$  region populated!**

# Cosmic String Explanation of NANOGrav Result

- ▶ solutions in the range  $10^{-11} \lesssim G\mu \lesssim 10^{-6}$
- ▶ agreement with Ellis and Lewicki (2009.06555) for  $\alpha = 0.1$

# Cosmic String Explanation of NANOGrav Result

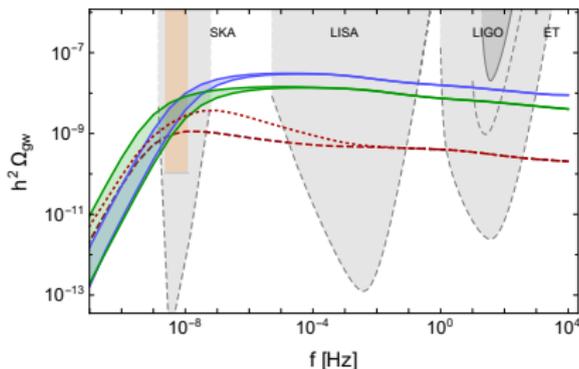

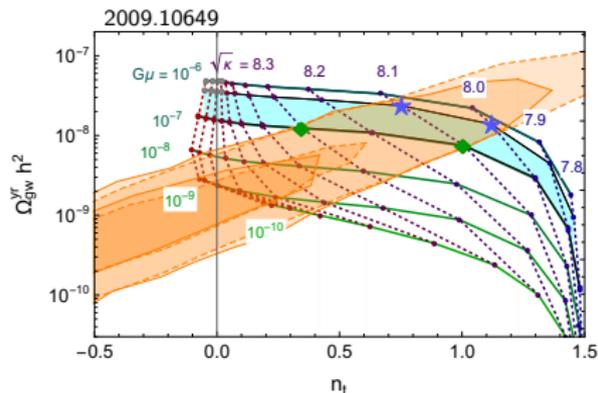

- ▶ The EPTA, PPTA, and NANOGrav curves at low frequencies represent the status of PTA constraints on the GW spectrum *prior to the new NANOGrav result*

- ▶ 
$$h^2\Omega_{\text{gw}}^{\text{plateau}} \simeq 2 \times 10^{-4} \left( \frac{\max\{\alpha, 9/4\Gamma G\mu\}}{0.1} \right)^{1/2} \left( \frac{G\mu}{\Gamma} \right)^{1/2}$$

- ▶ the expected spectrum is within the sensitivity reach of LISA, DECIGO, BBO, the *Einstein Telescope*, and *Cosmic Explorer*
- ▶ LIGO+Virgo+KAGRA will not be able to detect the signal at a sufficient signal-to-noise ratio **but...**

# Metastable Cosmic Strings and NANOGrav

- ▶ embedding U(1) model into some GUT model, e.g., SO(10) makes the entire string network unstable  $\implies$  existence of magnetic monopoles
- ▶ long strings and loops can decay to monopole-antimonopole pairs which can efficiently annihilate (arXiv:0808.1693)
- ▶ decay rate per unit length  $\Gamma = \frac{\mu}{2\pi} \text{Exp}[-\pi\kappa]$ , with  $\kappa = m^2/\mu$
- ▶ larger values than those in case of stable cosmic strings can fit NANOGrav (2009.10649)  $\implies$  possible signal at LIGO+Virgo+KAGRA

## Summary

- ▶ The **NANOGrav** collaboration recently reported strong evidence for a stochastic common spectrum process across the pulsars in its 12.5-year data set
- ▶ we investigated the results of the NANOGrav analysis based on the assumption that this stochastic process corresponds to a primordial SGWB emitted by **cosmic strings** in the early Universe
- ▶ we identified the viable cosmic-string parameter space and argued that the entire viable parameter region will be probed **in future GW experiments**
- ▶ NANOGrav signal points to symmetry breaking scales in the range  $v \sim 10^{16} \text{ GeV} \left( \frac{G\mu}{10^{-7}} \right)^{1/2} \sim 10^{14} \dots 10^{16} \text{ GeV}$ , (hep-ph/9411342)
