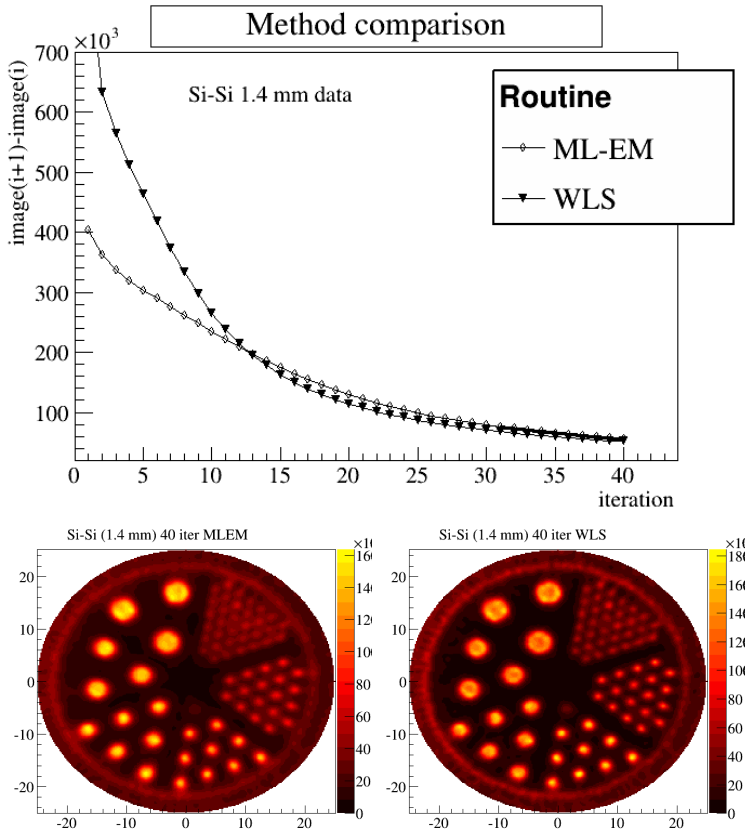
Alternative reconstruction methods: WLS



WLS:

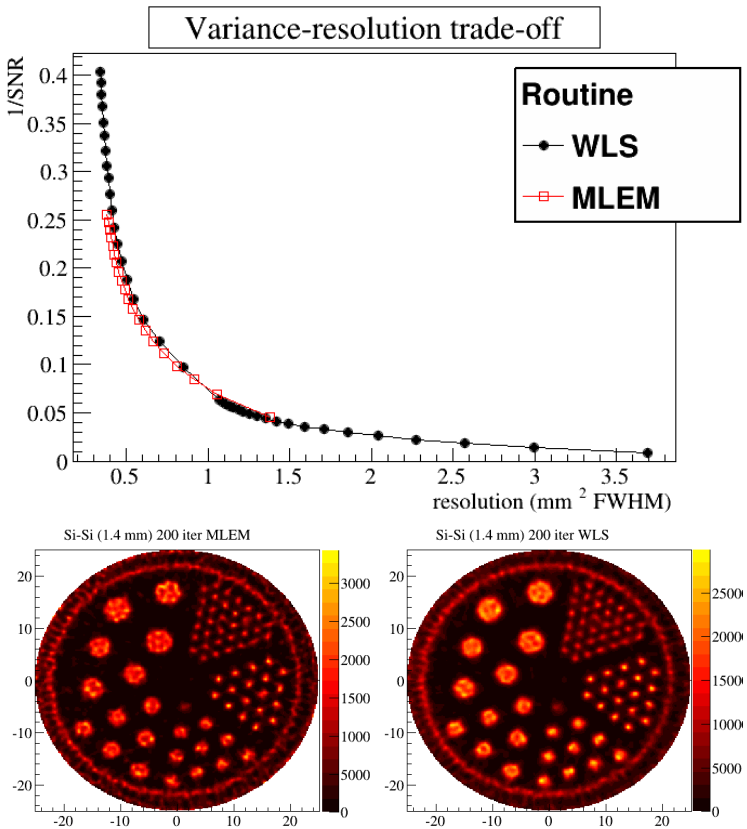
$$\chi^2 = (\mathbf{y} - A\boldsymbol{\lambda})^T C(\mathbf{y} - A\boldsymbol{\lambda})$$
$$C = diag^{-1}(A\boldsymbol{\lambda})$$

Benefits:

- PDF is defined for x$\in \Re$.
- Negligibly more complex:

$$\lambda_i^+ = \frac{\lambda_i}{S_i} \sum_j A_{ji} \frac{y_j^2}{(A\boldsymbol{\lambda})_j^2} \qquad (1)$$

WLS and MLEM comparison



WLS:

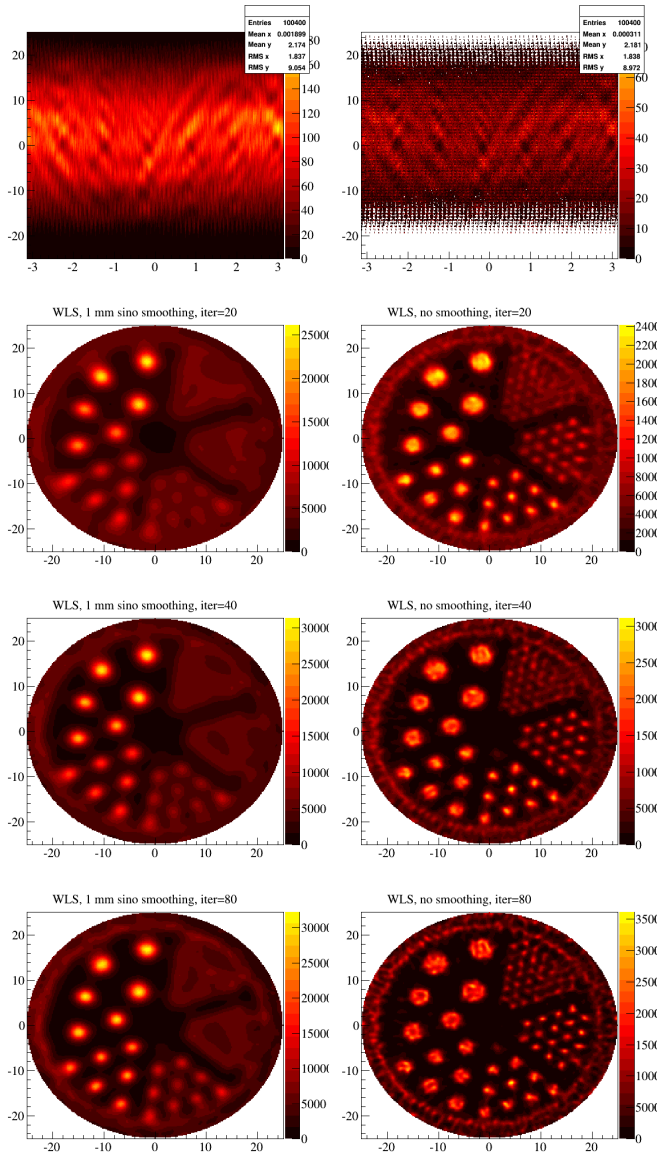
- Require equal projected and measured sinogram count:

$$\sum_k (A\lambda)_k = \sum_k y_k$$

- Iteration step modified to:

$$\lambda_i^+ = \frac{\sum_k y_k}{\sum_k \frac{y_k^2}{(A\lambda)_k}} \frac{\lambda_i}{S_i} \sum_j A_{ji} \frac{y_j^2}{(A\lambda)_j^2} \quad (2)$$

Sinogram smoothing



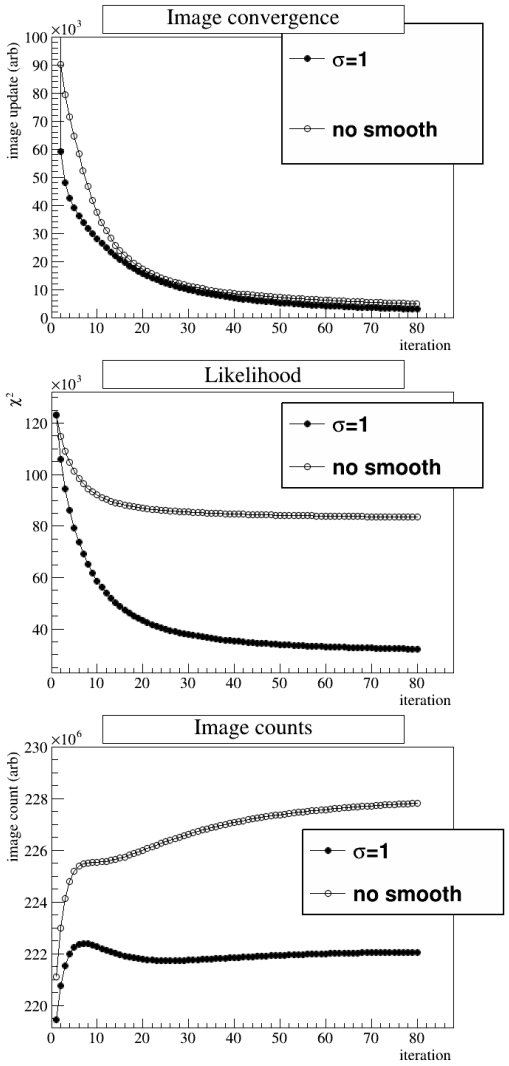
Sinogram smoothing:

$$\mathbf{y}' = W\mathbf{y}$$
$$A' = WA$$

W is a square matrix in sinogram space

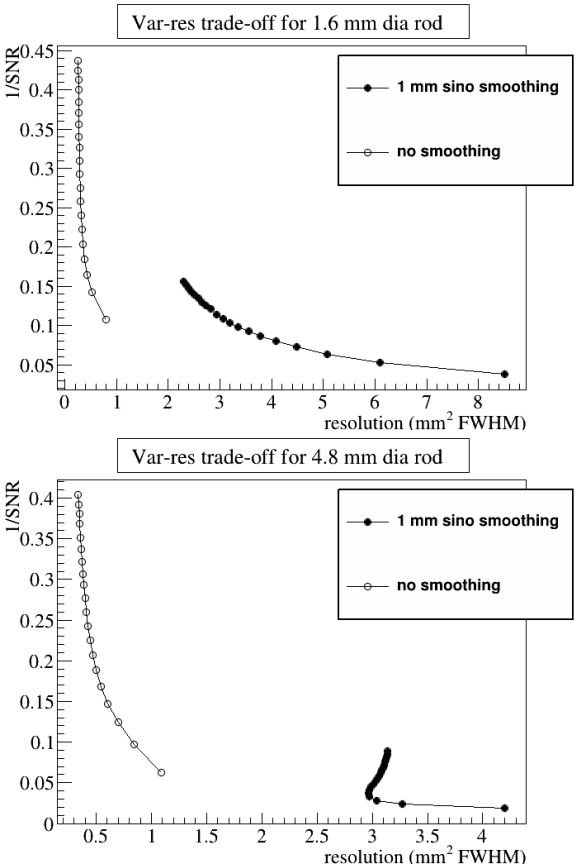
- In our case, smooting is a Gaussian σ wide along p

Convergence parameters



- Similar properties
- Better convergence of smoothed images, if anything

Smoothing high-res data: iter 200



- Smoothing of 1.6 and 4.8 mm rods
